

Introduction

Preliminaries

Tensors encapsulate multilinear maps. Often given as a multiway array of numbers, they are used across various disciplines of mathematics to record information for some fixed reference frame. As such, they are studied from many complementary perspectives [4] [16] [17] [20] [12] [21].

Throughout, we fix a field K . A tensor space T is a vector space equipped with an interpretation of its elements as a multilinear map, defined as $\langle \cdot | : T \hookrightarrow (U_n \times \cdots \times U_1 \rightharpoonup U_0)$ for U_i each a K -vector space. A tensor t is an element of a tensor space T . We say the spaces $\{U_0, \dots, U_n\}$ are the frame of tensor, and n the valence. For $|u\rangle = |u_n, \dots, u_1\rangle$, write $\langle t|u\rangle \in U_0$ to mean evaluating $\langle t|$ at $|u\rangle$. With this definition, given some $a \times b$ matrix of numbers $[t_{ij}]$, interpret it as a multilinear map $\langle t| : K^a \times K^b \rightharpoonup K$ where $\langle t|e_a^{(i)}, e_b^{(j)}\rangle = t_{ij}$. This extends to cubes of numbers and so on, so our definition interoperates with the popular model of tensors as dense grids of numbers.

The perspective taken in this dissertation proposal is to study tensors as distributive products using the tools of algebra. Fix a 3-tensor (bimap) $* : U \times V \rightharpoonup W$. Existing work such as [10], and [26] highlights the role of the commutative centroid algebra

$$\text{Cen}(t) := \{\sigma \in \text{End}(U) \times \text{End}(V) \times \text{End}(W) : \sigma u * v = u * \sigma v = \sigma(u * v) \forall u \in U, v \in V\},$$

associative adjoint algebra

$$\text{Adj}(t) := \{\sigma \in \text{End}(U)^{op} \times \text{End}(V) : u\sigma * v = u * \sigma v\},$$

and Lie derivation algebra

$$\text{Der}(t) := \{\delta \in \text{End}(U) \times \text{End}(V) \times \text{End}(W) : \delta u * v + u * \delta v = \delta(u * v)\}.$$

Existing work using this approach include discovering basis independent cluster pattern in tensors [5], decomposing p -groups [23], finding direct product decomposition of groups [24], and advances in isomorphism testing [7] [11] [9].

Two avenues of study are proposed for my dissertation, split between work on faster algorithms to compute these algebras, and work to prove structure and recognition theorems for specific classes of tensors using these algebras.

Summary of work on algorithms side

On the algorithms side, the computation of algebras $\text{Adj}(t)$, $\text{Cen}(t)$, and $\text{Der}(t)$ are given by linear equations. However, due to the large number of constraints and variables, they are bottlenecks for existing tensor methods. Even with subsampling, they are cubic in the number of variables. For roughly cubic tensors of dimension n for each vector space in the frame, this is at minimum $O(n^6)$ operations. In collaboration with James Wilson and Joshua Maglione, we have preliminary results for an asymptotically faster algorithm in computing $\text{Adj}(t)$ and $\text{Cen}(t)$ in $O(n^3)$ operations, inspired by analogous results for matrices known as the Bartels-Stewart algorithm [1]. My proposed work is to explore asymptotic speedups for the computation of $\text{Der}(t)$ in the 3-tensor case, and to extend to higher valence tensors in general.

Summary of work on theory side

On the theory side, for a tensor t we further investigate what basis-independent information are locked behind the algebraic invariants of t . My proposed work involves proving structure and recognition theorems for tensors combined by *soldering*, a generalization of the tensor product of

algebras. As X-rays are able to create images of internal structures for diagnostic purposes, we call this X-raying tensors.

We begin with a survey of existing work which informs the class of tensors we wish to investigate. Wilson in [26] [24] [23] [25] proves for bimap the algebras $\text{Adj}(t)$ and $\text{Cen}(t)$ control direct sum decompositions and automorphisms of t , using them to prove properties for the originating algebraic structures. Recent work generalizing from bimap finds a long exact sequence linking the various nuclei (generalized adjoints), centroids, and derivations of a higher valence tensor [8]. Further work by First, Maglione, and Wilson [13] defines a ternary Galois connection between tensors, operators, and polynomial ideals. Alongside it, they define a multivalent generalization of the Whitney tensor product on vector spaces U_1, \dots, U_n , parametrized by operators $\Omega \subset \prod_i \text{End}(U_i)$ and polynomials $P \subset K[x_1, \dots, x_n]$. The notation $\blacktriangleleft U_1, \dots, U_n \blacktriangleright_\Omega^P$ is used to indicate the (P, Ω) -tensor product on vector spaces. Let \mathbf{d} be the polynomial $x_n + \dots + x_0$. It is proven for a tensor t , the $(\mathbf{d}, \text{Der}(t))$ -tensor product is universally the smallest amongst the (P, Ω) -products that t factors through, for which $P \subset K[x_1, \dots, x_n]$ is an ideal generated by linear homogeneous polynomials. This motivates studies of $\text{Der}(t)$ and the associated $(\mathbf{d}, \text{Der}(t))$ -tensor product space.

For the remainder of the introduction, let $U_0 = k$. Then as investigated in [9], the vector space of tensors denoted $\langle t \rangle$ (derivation closure of t) consisting of tensors t' whose derivation algebra contains the derivation algebra of t , may be identified with the $(\mathbf{d}, \text{Der}(t))$ -tensor product space $\blacktriangleleft U_1, \dots, U_n \blacktriangleright_{\text{Der}(t)}^{\mathbf{d}}$ and thus is universally the smallest search space for solving tensor isomorphism questions involving t . In [9], an infinite family of tensors $\dim \langle t \rangle = 1$ in [9] is constructed. However, little else is known about $\langle t \rangle$. By Theorem B of [13], a basis for the space $\langle t \rangle$ is computable in polynomial time, so computational examples are available in practice.

We now describe the class of tensors to be studied. For tensors s and t with interpretations $\langle s | : \prod_{i=1}^n U_i \rightarrow K$ and $\langle t | : \prod_{i=1}^n V_i \rightarrow K$, define the tensor product of K -tensors s and t as $\langle s \otimes t | : \prod_{i=1}^n (U_i \otimes V_i) \rightarrow K$, where $\langle s \otimes t | u \otimes v \rangle = \langle s | u \rangle \langle t | v \rangle$. This we call *soldering* the tensors s and t together, due to the output tensor having the same valence as the inputs. This construction is used to construct an example of a tensor with decomposition detectable by the derivation algebra in [8]. We view it as generalizing the tensor product of algebras construction to arbitrary tensors with the same valence. For instance, given $\langle s | : K^2 \times K^2 \rightarrow K$ the dot product on K , and $\langle t | : L \times L \rightarrow L$ the multiplication tensor of some extension field L of K , the soldered tensor $\langle s \otimes t |$ is the dot product on L , since $\langle s \otimes t | : (K^2 \otimes L) \times (K^2 \otimes L) \rightarrow (K \otimes L) \cong L^2 \times L^2 \rightarrow L$. We have done an extension of scalars in this instance - itself a specific case of tensor product of algebras - on the dot product of vector spaces.

Computationally, we observe for soldered tensors that $\dim \langle s \rangle \otimes \langle t \rangle = \dim \langle s \otimes t \rangle$ for all known examples that would compute in a reasonable time. This we wish to investigate further. It is important to clarify the \otimes on the left hand side is the Whitney tensor product of vector spaces, while \otimes on the right is soldering the tensors s and t , and the spaces are identified by natural isomorphism.

Fix isomorphisms between the vector spaces U_i and its dual, as well as V_i and its dual. Then s having multilinear interpretation $\langle s | : \prod_i U_i \rightarrow K$, can be identified with an element of $(\bigotimes_i U_i)^*$. Because of the fixed isomorphisms to the duals, we can further identify s as an element of $U := \bigotimes_i U_i$. Similarly, t may be identified as an element of $V := \bigotimes_i V_i$. Let $\eta : U \otimes V \rightarrow \bigotimes_{i=1}^n (U_i \otimes V_i)$ be the natural isomorphism arising from the tensor products natural isomorphism $(A \otimes B) \otimes C \cong A \otimes (B \otimes C)$.

Treating $s \in U$ and $t \in V$ as vectors and denoting $s \otimes_K t$ as the image of (s, t) under the Whitney tensor product, we see $\eta(s \otimes_K t)$ is precisely the tensor arising from soldering s and t , which we denote $s \otimes t$ without the K subscript. Furthermore, the soldering of tensors is equivalent to $\eta(\blacktriangleleft s, t \blacktriangleright_\emptyset^\emptyset)$. This entails a study of soldered tensors as generalized (P, Ω) -tensor products.

In related works, the physics community uses techniques like the Density Matrix Renormalization Algorithm [22] attempts to uncover the structure of a high valence tensor by factoring it as a contracted product of 3-tensors called a Matrix Product State. This iterative optimization tech-

nique is for complex-valued tensors, relying on the Singular Value Decomposition. Techniques such as Tensor-Train decompositions and Tucker decompositions are similar but assumes different fixed internal structure. [16] Other tensor factorization techniques such as CP-decomposition [15] attempts to decompose a tensor as a sum of smaller tensors, whereas the soldering of tensors is a product of tensors.

Problems and Methodology

In this section, we outline the proposed problems we are investigating and contributions we foresee as part of this dissertation.

Algorithms Contribution Proposal

We wish to compute $\text{Adj}(t)$, $\text{Cen}(t)$, and $\text{Der}(t)$ for a bimap t . For fixed bases, each of the 3 algebras are specified by linear systems of equations, and thus can be computed in a number of steps polynomial to the sum of dimensions. But the naive solution has complexity cubic in the number of variables. We aim to do better in the general case.

Simultaneous Sylvester Equations

We report on results in collaboration with James Wilson and Joshua Maglione. First, the problem of computing adjoints of bimap is stated in coordinates. Next, we describe our approach, which is to translate the problem to a coordinate free formulation, solve a smaller subproblem, and propagate the subproblem solution to a full solution.

Problem 0.1 (Simultaneous Sylvester System - Coordinatized).

Given arrays $R \in K^{r \times b \times c}$, $S \in K^{a \times s \times c}$, and $T \in K^{a \times b \times c}$

Return matrices $X \in K^{a \times r}$ and $Y \in K^{s \times b}$ such that

$$(\forall i)(XR_i + S_iY = T_i). \quad (0.1)$$

Expressed as list of matrix equation, it is the natural extension of the Sylvester Equation, which asks for a single matrix equation $XA + BX = C$. For R and S filled in from a tensor with a fixed basis, and T to be all zero, solving an instance of this problem finds the adjoint algebra of the tensor. Below gives a coordinate free description.

Problem 0.2 (Simultaneous Sylvester System - Coordinate Free).

Given Elements $r \in R \otimes B \otimes C$, $s \in A \otimes S \otimes C$, $t \in A \otimes B \otimes C$, and isomorphisms identifying each vector space with its dual.

Return Elements $x \in \text{Hom}(A, R)$ and $y \in \text{Hom}(B, S)$ such that $(x \otimes I_B \otimes I_C)(r) + (I_A \otimes y \otimes I_C)(s) = t$.

First, by composing the isomorphism between R and its dual followed by the natural isomorphism $R^* \otimes B \otimes C \cong \text{Hom}(R, B \otimes C)$, we view r as an element of $\text{Hom}(R, B \otimes C)$. Similarly, view s as an element of $\text{Hom}(S, A \otimes C)$. We now look for subspaces $B' \leq B$ and $A' \leq A$ such that r and s have left inverses after post-composing with projections. We also need B' and A' to have an induced isomorphism to their respective duals. That is, we want $r_{B'} := (\pi_{B'} \otimes I_C) \circ r$ and $s_{A'} := (\pi_{A'} \otimes I_C) \circ s$ to have left inverses. Denote these left inverses as $r_{B'}^\#$ and $s_{A'}^\#$. For the second condition, the isomorphism $B \cong B^*$ needs to restrict an isomorphism $B' \cong (B')^*$, and similar for $A \cong A^*$ restricting to $A' \cong (A')^*$.

Now considering a projection to the spaces A' and B' , we compute

$$\begin{aligned}
& (\pi_{A'} \otimes \pi_{B'} \otimes I_C)((x \otimes I_B \otimes I_C)(r) + (I_A \otimes y \otimes I_C)(s)) = (\pi_{A'} \otimes \pi_{B'} \otimes I_C)(t) \\
& \iff (\pi_{A'} \otimes \pi_{B'} \otimes I_C)((x \otimes I_B \otimes I_C)(r)) + (\pi_{A'} \otimes \pi_{B'} \otimes I_C)((I_A \otimes y \otimes I_C)(s)) = (\pi_{A'} \otimes \pi_{B'} \otimes I_C)(t) \\
& \iff ((\pi_{A'} \circ x) \otimes (\pi_{B'} \circ I_B) \otimes (I_C \circ I_C))(r) + ((\pi_{A'} \circ I_A) \otimes (\pi_{B'} \circ y) \otimes (I_C \circ I_C))(s) = (\pi_{A'} \otimes \pi_{B'} \otimes I_C)(t) \\
& \iff (x_{A'} \otimes \pi_{B'} \otimes I_C)(r) + (\pi_{A'} \otimes y_{B'} \otimes I_C)(s) = (\pi_{A'} \otimes \pi_{B'} \otimes I_C)(t) \quad \text{for } x_{A'} := \pi_{A'} \circ x \text{ and } y_{B'} := \pi_{B'} \circ y
\end{aligned}$$

Solving for $x_{A'}$ and $y_{B'}$ proceed by standard linear algebra, but as $\dim x_{A'} = \dim A' \cdot \dim R$ and $\dim y_{B'} = \dim B' \cdot \dim S$, this smaller system have unknowns of considerably lower dimension if the subspaces A' and B' are lower dimensional compared to A and B .

After solving for $x_{A'}$ and $y_{B'}$ by conventional methods, our algorithm proceeds by finding complementary subspaces $A = A' \oplus U$, and $B = B' \oplus V$. Let r_V , s_U , x_U , and y_V be defined analogously to above. Then projecting to the subspaces A' and V , we require $(\pi_{A'} \otimes \pi_V \otimes I_C)((x \otimes I_B \otimes I_C)(r) + (I_A \otimes y \otimes I_C)(s)) = (\pi_{A'} \otimes \pi_V \otimes I_C)(t)$.

Using the fixed isomorphism between vector spaces and their duals, as well as the natural isomorphisms above, we see that

$$\begin{aligned}
& (\pi_{A'} \otimes \pi_V \otimes I_C)((x \otimes I_B \otimes I_C)(r) + (I_A \otimes y \otimes I_C)(s)) = (\pi_{A'} \otimes \pi_V \otimes I_C)(t) \\
& \iff (\pi_{A'} \otimes \pi_V \otimes I_C)((x \otimes I_B \otimes I_C)(r)) + (\pi_{A'} \otimes \pi_V \otimes I_C)((I_A \otimes y \otimes I_C)(s)) = (\pi_{A'} \otimes \pi_V \otimes I_C)(t) \\
& \iff (x_{A'} \otimes \pi_V \otimes I_C)(r) + (\pi_{A'} \otimes y_V \otimes I_C)(s) = (\pi_{A'} \otimes \pi_V \otimes I_C)(t) \\
& \iff (x_{A'} \otimes I_C) \circ r \circ \pi_V + (\pi_{A'} \otimes I_C) \circ s \circ y_V = (\pi_{A'} \otimes I_C) \circ t \circ \pi_V \quad \text{because } A' \otimes V \otimes C \cong \text{Hom}(V, A' \otimes C) \\
& \iff (x_{A'} \otimes I_C) \circ r_V + s_{A'} \circ y_V = (\pi_{A'} \otimes I_C) \circ t \circ \pi_V
\end{aligned}$$

Given $x_{A'}$, the only unknown in the last equation is y_V . Hence precomposing with $s_{A'}^\#$ to both sides gives a unique y_V solution. Analogously projecting to the subspaces U and B' followed by precomposing $r_{B'}^\#$ solves for a unique x_U given a $y_{B'}$. Finally, projecting to the subspaces U and V verifies the overall equation is satisfied for the pair x_U, y_V .

In summary, our algorithm requires the user to provide in addition to the data of the problem the subspace A' and B' with the desired invertibility properties of $r_{B'}$ and $s_{A'}$. In coordinates, the linear transformation $r \in \text{Hom}(R, B \otimes C)$ has $bc := \dim B \otimes C$ rows and $r := \dim R$ columns, thus projecting to a $\dim \lceil r/c \rceil$ subspace of B have a high probability of maintaining the left invertibility of r .

TODO: Talk about how a naive guess of A' and B' will succeed in most cases and speed up the “common” case of the Sylvester equations, and in the cubic case, this translates to the $O(n^6)$ to $O(n^3)$ improvement.

Derivation System

Extending the above approach to computing derivations of bimaps is a part of my dissertation proposal. First to state the problem in coordinates, we need

Definition 0.3 (Outer action). *Given an array $T \in K^{a \times b \times d}$, let $[T_1, \dots, T_d]$ be a list of $K^{a \times b}$ matrices corresponding to unfolding this array along the third index,. Then for a matrix Z of size $d \times c$, define T^Z , the outer action of Z on T , as the $K^{a \times b \times c}$ array satisfying $(T^Z)_j = \sum_{i=1}^d T_i Z_{ij}$.*

Problem 0.4 (Derivation system - Coordinatized).

Given arrays $R \in K^{r \times b \times c}$, $S \in K^{a \times s \times c}$, and $T \in K^{a \times b \times t}$

Return matrices $X \in K^{a \times r}$, $Y \in K^{s \times b}$, and $Z \in K^{t \times c}$ such that

$$(\forall i) X R_i + S_i Y + (T^Z)_i = 0. \tag{0.2}$$

The above equation is no longer a list of matrix equations due to the outer action by Z . But it is exactly the equation satisfied by the derivation algebra of a tensor when R, S, T are all filled in from a tensor in a fixed basis. We propose studying the coordinate free version of the problem below.

Problem 0.5 (Derivation system - Coordinate Free).

Given Elements $r \in R \otimes B \otimes C$, $s \in A \otimes S \otimes C$, $t \in A \otimes B \otimes T$, and isomorphisms identifying the vector spaces and their duals.

Return Elements $x \in \text{Hom}(A, R)$, $y \in \text{Hom}(B, S)$, and $Z \in \text{Hom}(C, T)$ such that $(x \otimes I_B \otimes I_C)(r) + (I_A \otimes y \otimes I_C)(s) + (I_A \otimes I_B \otimes z)(t) = 0$.

Preliminary investigations suggest a similar approach to Problem 0.1 but with 3 subspaces, $A' \leq A$, $B' \leq B$, and $C' \leq C$. Additional work is needed to prove a faster solution exists, analyze its complexity, and implement in code.

Thus far we have only been concerned about bimaps. We propose extending the above ideas to higher valence tensors. The problem to solve is framed in context of solving for algebraic invariants of tensors as they do not clearly translate to matrix equations.

We first give notation for an endomorphism acting on a specific axis of the tensor.

Definition 0.6. Let $t : \prod_i U_i \rightarrow K$. Let $\sigma \in \text{End}(U_a)$. Then define the tensor $\langle t | \sigma$ as

$$\langle t | \sigma | u \rangle = \langle t | \sigma u_a, u_{\bar{a}} \rangle$$

Where $u = (u_a, u_{\bar{a}})$ splits $u \in \prod_i U_i$ as an element of $U_a \times \prod_{i \neq a} U_i$.

Problem 0.7. Let $t : \prod_{i \in I} U_i \rightarrow K$. Let $\{a, b\} \subset I$.

Generalizing the adjoint, define the ab -nucleus of t as

$$\text{Nuc}_{ab}(t) := \{(\sigma_a, \sigma_b) \in \text{End}(U_a) \times \text{End}(U_b) : \langle t | \sigma_a u_a, u_{\bar{a}} \rangle = \langle t | \sigma_b u_b, u_{\bar{b}} \rangle\}.$$

For $J \subset I$, define the J -centroid as

$$\text{Cen}_J(t) := \left\{ (\sigma_j)_{j \in J} \in \prod_j \text{End}(U_j) : \langle t | \sigma_j u_j, u_{\bar{j}} \rangle = \langle t | \sigma_k u_k, u_{\bar{k}} \rangle \forall j, k \in J \right\}.$$

Similary, define the J -derivation as

$$\text{Der}_J(t) := \left\{ (\delta_j)_{j \in J} \in \prod_j \text{End}(U_j) : \sum_j \langle t | \delta_j u_j, u_{\bar{j}} \rangle = 0 \right\}.$$

These spaces are computed by linear equations, and generalizes the adjoint and derivation equation of 3-tensors to higher valence tensors. We investigate if each of these algebras can be computed in operations less than cubic in the number of variables?

Theoretical Contribution Proposal

As described in the introduction, we wish to better understand soldered tensors by X-raying them using algebra. To state the problem, follow the exposition and notation in [13].

Definition 0.8. (*Ternary Galois Connection of Tensors, Ideals, and Operators*)

Fix a space of tensors $\text{Hom}(U_n \otimes \cdots \otimes U_1, U_0)$, a space of polynomials $K[X] := K[x_0, \dots, x_n]$, and a space of operators $E[U_0, \dots, U_n] := \text{End}(U_n) \times \cdots \times \text{End}(U_0)$. Note a tensor t in $\text{Hom}(U_n \otimes \cdots \otimes U_1, U_0)$ has the interpretation as a multilinear map $\langle t | : \prod_{i=1}^n U_i \rightarrow U_0$.

Then for $p = \sum_e \lambda_e X^e \in K[X]$ and $\omega \in E[U_0, \dots, U_n]$, define

$$p(\omega) := \sum_e \lambda_e (\omega_0^{e_0}, \dots, \omega_n^{e_n}) \in E[U_0, \dots, U_n].$$

For all $t \in \text{Hom}(U_n \otimes \cdots \otimes U_1, U_0)$, define the action of $p(\omega)$ on tensor t as the tensor $\langle t | p(\omega)$ where for any (u_1, \dots, u_n) ,

$$\langle t | p(\omega) | u \rangle = \sum_e \lambda_e \omega_0^{e_0} \langle t | \omega_1^{e_1} u_1, \dots, \omega_n^{e_n} u_n \rangle.$$

Now fix a polynomial p and operator ω . Define the set $T(p, \omega) := \{t \in \text{Hom}(U_n \otimes \cdots \otimes U_1, U_0) : \langle t | p(\omega) = 0\}$. Extend this definition to subsets P and Ω via

$$T(P, \Omega) := \bigcap_{p \in P} \bigcap_{\omega \in \Omega} T(p, \omega).$$

Similarly, for fixed polynomial p and tensor t define the set $Z(t, p) := \{\omega \in E[U_n, \dots, U_0] : \langle t | p(\omega) = 0\}$ and extend to subsets $Z(T, P)$. Fixing $P \subset K[X]$, there is an inclusion reversing Galois connection between subsets of tensors and operators

$$S \subset T(P, \Omega) \iff \Omega \subset Z(S, P) \quad (0.3)$$

From [13] the set $T(P, \Omega)$ is a vector subspace of $\text{Hom}(U_n \otimes \cdots \otimes U_1, U_0)$ and $Z(S, \mathbf{d})$ is a Lie algebra for $\mathbf{d} = x_n + \cdots + x_0$.

Definition 0.9. (*Derivation closure*) Let $s \in \text{Hom}(U_n \otimes \cdots \otimes U_1, U_0)$. Then $\langle s |$, the derivation closure of s , is the vector subspace consisting of all tensors t such that $\text{Der}(s) \subset \text{Der}(t)$. Hence $\langle s | := T(\mathbf{d}, Z(\mathbf{d}, s))$.

Definition 0.10. (*Soldering of tensors*) Let $\langle s | : \prod_i U_i \rightarrow U_0$ and $\langle t | : \prod_i V_i \rightarrow V_0$. The soldering of s and t is the tensor $s \otimes t$ is the multilinear map $\langle s \otimes t | : \prod_i U_i \otimes V_i \rightarrow U_0 \otimes V_0$ defined by $\langle s \otimes t | u \otimes v = \langle s | u \otimes \langle t | v$.

Remark 0.11. Let $\langle s | : \prod_i U_i \rightarrow K$ and $\langle t | : \prod_i V_i \rightarrow K$. Define $U := \bigotimes_i U_i$ and $V := \bigotimes_i V_i$. Let $\hat{s} \in U$, $\hat{t} \in V$ be the elements identified with s and t using the Whitney tensor product universal property and dual space isomorphism. When not ambiguous, we shall say $s \in U$. Similarly, the soldered multilinear map $\langle s \otimes t | : \prod_i U_i \otimes V_i \rightarrow K$ is identified with $\widehat{s \otimes t} \in \bigotimes_i (U_i \otimes V_i)$, and we shall also say $s \otimes t \in \bigotimes_i (U_i \otimes V_i)$ when not ambiguous.

We now pause to resolve an ambiguity in $s \otimes t$. From above, $s \otimes t$ may be shorthand for $\widehat{s \otimes t} \in \bigotimes_i (U_i \otimes V_i)$, which is naturally identified with $\langle s \otimes t |$. Alternatively, identifying s with $\hat{s} \in U$ and t with $\hat{t} \in V$ as vectors, $s \otimes t \in U \otimes V$ is the image of (\hat{s}, \hat{t}) by the Whitney tensor product. This ambiguity is resolved up to the natural isomorphism $\eta : U \otimes V \rightarrow \bigotimes_{i=1}^n (U_i \otimes V_i)$. When disambiguation is needed, the notation $s \otimes_K t$ will refer to the Whitney tensor product of s and t , thought of as vectors. The above discussion extends to the sum $\sum_{i=1}^n u_i \otimes v_i$ for $u_i \in U$ and $v_i \in V$.

Below we summarize the theoretical results we plan on working towards, listed in order of concreteness. Perhaps not surprisingly, these problems are also ordered by the current amount of insight we have towards a solution to each.

We begin with the case of analyzing the derivation closure of tensors that are soldered together.

Problem 0.12 (Soldered tensors derivation closure).

Given $\langle s | : \prod_{i=1}^n U_i \rightarrow K$ and $\langle t | : \prod_{i=1}^n V_i \rightarrow K$, how does $\langle s |$ and $\langle t |$ relate to $\langle s \otimes t |$?

We have recently resolved this first problem. Let $U, V, \hat{s}, \hat{t}, \widehat{s \otimes t}$ be defined as above. Below is a preliminary lemma.

Lemma 0.13. For $\langle s | : \prod_{i=1}^n U_i \rightarrow K$, $\langle t | : \prod_{i=1}^n V_i \rightarrow K$, there are embeddings $\iota_s : \text{Der}(s) \hookrightarrow \text{Der}(s \otimes t)$ given by $(\sigma_i)_{i \in [n]} \mapsto (\sigma_i \otimes I_{V_i})_{i \in [n]}$ and $\iota_t : \text{Der}(t) \hookrightarrow \text{Der}(s \otimes t)$ given by $(\tau_i)_{i \in [n]} \mapsto (I_{U_i} \otimes \tau_i)_{i \in [n]}$.

Proof. The map ι_i is injective on each factor as tensoring with the identity morphism is injective. The endomorphism $(\sigma_i \otimes I_{V_i})_{i \in [n]}$ is in $\text{Der}(s \otimes t)$ as $\langle s \otimes t | \mathbf{d}((\sigma_i \otimes I_{V_i})_{i \in [n]}) = \sum_{i=1}^n \langle s | \sigma_i \otimes \langle t | I_{V_i} = \langle s | \mathbf{d}((\sigma_i)_{i \in [n]}) \otimes \langle t | = 0$. Lastly, we need to demonstrate ι_i is a map of Lie algebras. This follows by the calculation $\iota(\delta + \rho) = \iota((\delta_i + \rho_i)_{i \in [n]}) = ((\delta_i + \rho_i) \otimes I_{V_i})_{i \in [n]} = (\delta_i \otimes I_{V_i})_{i \in [n]} + (\rho_i \otimes I_{V_i})_{i \in [n]} = \iota(\delta) + \iota(\rho)$. The case for ι_j is analogous. This concludes the proof. \square

Theorem 0.14. There is a natural isomorphism between the vector spaces $\langle s | \otimes \langle t | \leq U \otimes V$ and $\langle s \otimes t | \leq \bigotimes_{i=1}^n (U_i \otimes V_i)$, given by the restriction of the natural isomorphism $\eta : U \otimes V \rightarrow \bigotimes_{i=1}^n (U_i \otimes V_i)$.

Proof. Our strategy is to show $\langle s \otimes t | \subset \eta(\langle s | \otimes \langle t |)$ and $\eta(\langle s | \otimes \langle t |) \subset \langle s \otimes t |$.

$\langle s \otimes t | \subset \eta(\langle s | \otimes \langle t |)$:

By Lemma 0.13, there are embeddings $\iota_s : \text{Der}(s) \hookrightarrow \text{Der}(s \otimes t)$ and $\iota_t : \text{Der}(t) \hookrightarrow \text{Der}(s \otimes t)$. The inclusion reversing nature of the antitone Galois connection in Definition 0.8 implies $\langle s \otimes t | = T(\mathbf{d}, \text{Der}(s \otimes t)) \subset T(\mathbf{d}, \iota_s(\text{Der}(s)))$ and $\langle s \otimes t | \subset T(\mathbf{d}, \iota_t(\text{Der}(t)))$. Thus $\langle s \otimes t |$ is in their intersection. We shall prove $T(\mathbf{d}, \iota_s(\text{Der}(s))) = \eta(\langle s | \otimes V)$ and $T(\mathbf{d}, \iota_t(\text{Der}(t))) = \eta(U \otimes \langle t |)$. The conclusion follows as $\langle s \otimes t | \subset \eta(\langle s | \otimes V) \cap \eta(U \otimes \langle t |) = \eta(\langle s | \otimes \langle t |)$.

The statement to prove is $T(\mathbf{d}, \iota_s(\text{Der}(s))) = \eta(\langle s | \otimes V)$.

We first show the direction $\eta(\langle s | \otimes V) \subset T(\mathbf{d}, \iota_s(\text{Der}(s)))$. As $\langle s | \otimes V$ is generated by $\acute{s} \otimes_K t$ for $\acute{s} \in \langle s |$ and $t \in V$, it suffices to show $\eta(\acute{s} \otimes_K t) \in T(\mathbf{d}, \iota_s(\text{Der}(s)))$. This follows as $\langle \acute{s} \otimes t |$ satisfies $\langle \acute{s} \otimes t | \mathbf{d}(\delta) = 0$ for all $\delta = (\sigma_i \otimes I_{V_i})_{i \in [n]} \in \iota_s(\text{Der}(s))$ since $(\sigma_i)_{i \in [n]} \in \text{Der}(s)$.

In the opposite direction, by definition $T(\mathbf{d}, \iota_s(\text{Der}(s)))$ is a subspace of $\eta(U \otimes V)$. We shall show in fact it is the subspace $\eta(\langle s | \otimes V)$ by showing every element in $T(\mathbf{d}, \iota_s(\text{Der}(s)))$ is the image of sum of pure tensors $\acute{s} \otimes t$ under η for $\acute{s} \in \langle s |, t \in V$.

Let r be an element of $T(\mathbf{d}, \iota_s(\text{Der}(s)))$. Using η , identify r as $\sum_{i=1}^m s_i \otimes_K t_i \in U \otimes V$. Showing each s_i is in $\langle s |$ concludes r is in $\eta(\langle s | \otimes V)$. By definition r satisfies $\langle r | \mathbf{d}(\iota_s(\sigma)) = 0$ for all $\sigma \in \text{Der}(s)$. Ensure all t_i s linearly independent by collecting terms if necessary.

Let $\sigma \in \text{Der}(s)$ and $\iota_s(\sigma) = (\sigma_j \otimes I_{V_j})_{j \in [n]}$. Computing,

$$\begin{aligned}
0 &= \langle r | \mathbf{d}(\iota_s(\sigma)) \\
&= \left\langle \sum_i s_i \otimes t_i \middle| \mathbf{d}(\iota_s(\sigma)) \right\rangle \\
&= \sum_i \langle s_i \otimes t_i | \mathbf{d}(\iota_s(\sigma)) \rangle \quad \text{linearity of tensor evaluation} \\
&= \sum_i \left(\langle s_i \otimes t_i | \left(\sum_{j=1}^n \sigma_j \otimes I_{V_j} \right) \right) \\
&= \sum_i \left(\sum_{j=1}^n (\langle s_i \otimes t_i | \sigma_j \otimes I_{V_j}) \right) \quad \text{linearity of } \mathbf{d} \\
&= \sum_i \left(\sum_{j=1}^n (\langle s_i | \sigma_j \otimes t_i) \right)
\end{aligned}$$

$$\begin{aligned}
&= \sum_i \left(\sum_j \langle s_i | \sigma_j \rangle \right) \otimes t_i \\
&= \sum_i \langle s_i | \mathbf{d}(\sigma) \rangle \otimes t_i
\end{aligned}$$

Let $\{F_b\}_{b \in \mathcal{B}}$ be a basis of V . Then expanding each t_i in this basis,

$$\begin{aligned}
0 &= \sum_i \left(\langle s_i | \mathbf{d}(\sigma) \rangle \otimes \left(\sum_{b \in \mathcal{B}} \lambda_{ib} F_b \right) \right) \\
&= \sum_{b \in \mathcal{B}} \left(\sum_i (\lambda_{ib} \langle s_i | \mathbf{d}(\sigma) \rangle) \otimes F_b \right)
\end{aligned}$$

Since F_b are linearly independent, $\sum_i \lambda_{ib} \langle s_i | \mathbf{d}(\sigma) \rangle = 0$. Since t_i s are linearly independent, the m by $|\mathcal{B}|$ matrix $[\lambda_{ib}]$ has full row rank. Thus the only way $\sum_i \lambda_{ib} \langle s_i | \mathbf{d}(\sigma) \rangle = 0$ is if $\langle s_i | \mathbf{d}(\sigma) \rangle = 0$ for all i . Thus $s_i \in \langle s \rangle$ for all i . This concludes the proof of $T(\mathbf{d}, \iota_s(\text{Der}(s))) = \eta(\langle s \rangle \otimes V)$.

The statement $T(\mathbf{d}, \iota_t(\text{Der}(t))) = \eta(U \otimes \langle t \rangle)$ is proven analogously.

$\eta(\langle s \rangle \otimes \langle t \rangle) \subset \langle s \otimes t \rangle$:

The strategy will be to first show for $\acute{s} \in \langle s \rangle$, that $\acute{s} \otimes t \in \langle s \otimes t \rangle$, and secondly, show if $\acute{s} \otimes t \in \langle s \otimes t \rangle$ for all s , then for all $\acute{t} \in \langle t \rangle$, that $\acute{s} \otimes \acute{t} \in \langle s \otimes t \rangle$. Hence $\eta(\acute{s} \otimes_K \acute{t}) \in \langle s \otimes t \rangle$. The proof concludes as $\langle s \rangle \otimes \langle t \rangle$ is generated by $\acute{s} \otimes_K \acute{t}$ for $\acute{s} \in \langle s \rangle$ and $\acute{t} \in \langle t \rangle$, and

To show $\acute{s} \otimes t \in \langle s \otimes t \rangle$, let $\delta \in \text{Der}(s \otimes t)$. Since δ is an element of $\prod_i \mathfrak{gl}(U_i \otimes V_i) \cong \prod_i (\mathfrak{gl}(U_i) \otimes \mathfrak{gl}(V_i))$, write δ as $\left(\sum_{j=1}^{R_i} (\sigma_j \otimes \tau_j) \right)_{i \in [n]}$. By construction $\langle s \otimes t | \mathbf{d}(\delta) \rangle = 0$. Calculating,

$$\begin{aligned}
0 &= \langle s \otimes t | \mathbf{d}(\delta) \rangle \\
&= \langle s \otimes t | \sum_{i=1}^n \left(\sum_{j=1}^{R_i} (\sigma_j \otimes \tau_j) \right) \rangle \\
&= \langle s \otimes t | \sum_{a \in A} (\sigma_a \otimes \tau_a) \rangle \quad \text{grouping into one indexing set} \\
&= \sum_{a \in A} \langle s | \sigma_a \rangle \otimes \langle t | \tau_a \rangle \\
&= \sum_{a \in A} \langle s | \sigma_a \rangle \otimes \left(\sum_{b \in \mathcal{B}} \lambda_{ab} F_b \right) \quad \text{For } F_b \text{ basis of } V \\
&= \sum_{b \in \mathcal{B}} \left(\sum_{a \in A} \lambda_{ab} \langle s | \sigma_a \rangle \right) \otimes F_b
\end{aligned}$$

As $\{F_b\}_{b \in \mathcal{B}}$ is a basis of V , $\sum_{a \in A} \lambda_{ab} \langle s | \sigma_a \rangle = 0$ for each b . Regrouping and combining the terms in the indexing set A by axes, we have $\langle s | \sigma = 0$, meaning $\sigma \in \text{Der}(s)$. Thus $\langle \acute{s} | \sigma = 0$ as well. Substituting \acute{s} in place of s in the above equation also equals 0, concluding $\langle \acute{s} \otimes t | \mathbf{d}(\delta) \rangle = 0$.

The proof that $\acute{s} \otimes \acute{t} \in \langle s \otimes t \rangle$, assuming $\acute{s} \otimes t$ is in $\langle s \otimes t \rangle$ is analogous. This concludes the proof. \square

To describe extensions to the above problem we wish to investigate, define the (P, Ω) -tensor product.

Definition 0.15. ((P, Ω) -tensor product) [13]

Let U_1, \dots, U_n be K -vector spaces, $P \subset K[x_1, \dots, x_n]$ and $\Omega \subset \text{End}(U_1) \times \dots \times \text{End}(U_n)$. Define the following subspace of $U_1 \otimes \dots \otimes U_n$

$$\Xi(P, \Omega) := \left\langle \sum_e \lambda_e \omega_1^{e_1} u_1 \otimes \dots \otimes \omega_n^{e_n} u_n \mid \omega \in \Omega, \sum_e \lambda_e x_1 e^{e_1} \dots x_n e^{e_n} \in P, u_i \in U_i \right\rangle.$$

Define the (P, Ω) -tensor product space as the quotient space

$$\blacktriangleleft U_1, \dots, U_n \blacktriangleright_{\Omega}^P := (U_1 \otimes \dots \otimes U_n) / \Xi(P, \Omega),$$

together with a K -multilinear map $\blacktriangleleft \dots \blacktriangleright : U_1 \times \dots \times U_n \rightarrow \blacktriangleleft U_1, \dots, U_n \blacktriangleright_{\Omega}^P$ defined by $\blacktriangleleft u_1, \dots, u_n \blacktriangleright = u_1 \otimes \dots \otimes u_n + \Xi(P, \Omega)$.

Notice $\blacktriangleleft U_1, \dots, U_n \blacktriangleright_{\emptyset}^{\emptyset}$ is the usual Whitney tensor product. Suppose each U_i is of the form $\bigotimes_{j=1}^m V_i^j$, thus naturally identified under η with a tensor $s_i : \prod_j V_i^j \rightarrow K$. Then the output $\blacktriangleleft s_1, \dots, s_n \blacktriangleright$ can be naturally identified under η as a multilinear map $\prod_{j=1}^m \bigotimes_i V_i^j \rightarrow K$. This formulates the generalization of the soldering of tensors s and t . We wish to prove analogous statements for the tensor $\eta(\blacktriangleleft s_1, \dots, s_n \blacktriangleright_{\Omega}^P)$.

Next up, a related problem is to analyze the derivation algebras themselves to understand the tensor, rather than the tensor spaces.

Problem 0.16 (Soldered tensors derivations).

Given $s : \prod_i U_i \rightarrow U_0$ and $t : \prod_i V_i \rightarrow V_0$, how does $\text{Der}(s \otimes t)$ relate to $\text{Der}(s)$ and $\text{Der}(t)$?

We know for the case of adjoints, $\text{Adj}(s \otimes t) = \text{Adj}(s) \otimes \text{Adj}(t)$ [23], but nothing is known for $\text{Der}(s \otimes t)$ other than Lemma 0.13 above. Preliminary computations and dimension counting suggests the embeddings of $\text{Der}(s)$ and $\text{Der}(t)$ do not interact, as the dimension of $\text{Der}(s \otimes t)$ in the computed examples are close to the dimension of $\text{Der}(s) \cdot \text{Cen}(t) + \text{Der}(t) \cdot \text{Cen}(s)$.

The generalizations of the above problem will be investigated using the (P, Ω) -tensor product once the original problem is resolved. Given a list of tensors s_1, \dots, s_n , each s_i in the space $\bigotimes_j V_i^j$, what can we say about $\text{Der}(\eta(\blacktriangleleft s_1, \dots, s_n \blacktriangleright))$?

Insights into both previous problems should feed into solving the following problem.

Problem 0.17 (X-raying soldered tensors).

Given $r : \prod_{i=1}^n W_i \rightarrow W_0$, what are necessary and sufficient conditions to for $r = s \otimes t$ for some $s : \prod_{i=1}^n U_i \rightarrow U_0$ and $t : \prod_{i=1}^n V_i \rightarrow V_0$?

Here, the problem is to understand for which classes of soldered tensors does X-raying succeed? The tools at our disposal for this problem are the algebraic invariants of the tensor r , in addition to results on the previous problems and additional hypotheses on the structure of r .

Lastly, if there is enough time and the above problems come to a satisfactory conclusion, we'd like to investigate X-raying in a more general context. [8] produces a long exact sequence between the restricted centroids, ending at the derivations. We plan on following and extending this idea to understand how the various restricted derivation algebras interact and restrict a given tensor. An ideal outcome in this investigation is to find more general necessary and sufficient conditions for successful X-raying of tensors.

Definition 0.18. *TODO: Define the glued restricted derivation algebras $\bigoplus_A \text{Der}_A(t)$, citing from [8].*

Problem 0.19 (X-raying general tensors).

Given $t : \prod_i U_i \rightarrow U_0$, what are the necessary and sufficient conditions to ... **TODO.. this is the big "football" thing we talked about back in February, but it is not as well-defined due to me not having a clear example in mind.**

TODO: One other problem that came to me as I was writing is if it is possible to classify what can happen when we only solder a restricted class of tensors (e.g only algebras over a base field, drawing inspiration from Brauer group operation being the tensor product of algebras) this is extremely underbaked presently

Additional Applications

In addition to the application mentioned above to the study of tensors, we list some other uses to solutions of Problem 0.1.

TODO: This can be written last. The Sylvester equation applications are already written in QuickSylvester paper. Derivation applications have been mentioned, and some blurbs about X-raying can go here

Conclusion

Tensors are multilinear objects ubiquitous in the mathematics and the sciences. Studying tensors through algebraic invariants gives insight on the structure of the tensor independent of a chosen basis. That information is often useful to the source of the tensor. To that end, we propose two sides of work in our dissertation. Firstly, algorithmic work to compute these invariants more quickly through smart partitions of the involved vector spaces. Secondly, theoretical work to understand tensors that are soldered together from others.
